1 . Main points

In this bulletin, we report percentages of the population that are estimated to have antibodies against SARS-CoV-2, the specific virus that causes coronavirus (COVID-19) above varying levels.

In the week beginning 22 August 2022, the percentage of people estimated to have antibodies against SARS-CoV-2:

- in England, was 96.9% of adults at or above 179 nanograms per millilitre (ng/ml) (95% credible interval: 96.5% to 97.3%), and 75.0% of adults at or above 800 ng/ml (95% credible interval: 73.5% to 76.4%)
- in Wales, was 97.0% of adults at or above 179 ng/ml (95% credible interval: 96.3% to 97.5%), and 75.2% of adults at or above 800 ng/ml (95% credible interval: 73.0% to 77.3%)
- in Northern Ireland, was 96.4% of adults at or above 179 ng/ml (95% credible interval: 94.8% to 97.5%), and 78.9% of adults at or above 800 ng/ml (95% credible interval: 75.5% to 82.0%)
- in Scotland, was 96.2% of adults at or above 179 ng/ml (95% credible interval: 95.5% to 96.8%), and 74.6% of adults at or above 800 ng/ml (95% credible interval: 72.6% to 76.5%)
- in Great Britain for children aged 8 to 11 years, was 68.4% at or above 179 ng/ml (95% credible interval: 57.9% to 77.0%), and 50.9% at or above 800 ng/ml (95% credible interval: 40.6% to 60.8%)
- in Great Britain for children aged 12 to 15 years, was 93.0% at or above 179 ng/ml (95% credible interval: 89.2% to 95.6%), and 77.5% at or above 800 ng/ml (95% credible interval: 71.6% to 82.5%)

Estimates of antibodies against SARS-CoV-2 at the 800 ng/ml level are not comparable with our estimates published before 27 July 2022 because of method changes.

About this bulletin

In this publication, we include estimates of antibody positivity at the following thresholds: 179 ng/ml, 800 ng/ml, 2000 ng/ml, 4000 ng/ml and 6000 ng/ml.

Our 179 ng/ml level is based on research by our academic partners and reflects the percentage of adults who would have been likely to have a sufficiently strong antibody response to provide some protection from getting a new COVID-19 infection with the Delta variant. It is unlikely that this level will provide equivalent protection against the Omicron variant. Antibody levels below this 179 ng/ml level do not necessarily mean that a person has no antibodies or immune protection at all.

We have introduced estimates of antibody positivity at higher levels to enable enhanced monitoring of antibody levels and waning. These levels are not based on academic research on protection against Omicron, as sufficient evidence is not yet available. The 800 ng/ml level is the highest level at which we can produce a historic series back to December 2020. In this publication, we also introduce estimates of antibody positivity at 2000 ng/ml, 4000 ng/ml, and 6000 ng/ml, which are available from 2 May 2022. These thresholds are provided to enable enhanced monitoring against antibody waning, but we are likely to continue to develop our method for producing these estimates, and historical estimates may therefore change.

Further details of recent method changes to incorporate these higher threshold levels can be found in our [Coronavirus \(COVID-19\) Infection Survey, antibody data, UK: 27 July 2022](#) publication.

The data collection method for the Coronavirus (COVID-19) Infection Survey (CIS) has recently changed from study worker visits to remote data collection. For more information, see our [Measuring the data](#) section. Our antibody positivity estimates are subject to continuous review as the coronavirus pandemic evolves.

As part of our continuous improvement, a small percentage of samples are being retested where a conclusive result was not previously obtained. Some of these samples have now been retested, and estimates of antibody positivity have been updated accordingly, with minimal impact on results.

2 . Antibodies by age group

In the week beginning 22 August 2022, the percentage of the adult population estimated to have antibodies against SARS-CoV-2 at or above the level of 179 nanograms per millilitre (ng/ml) remained high across the UK. Among those aged 75 years and over, the percentage estimated to have antibodies against SARS-CoV-2 at or above the level of 800 ng/ml has generally increased since April 2022. This is likely as a result of fourth vaccinations given to people of those ages, although there are early indications that levels could be beginning to decrease.

Figure 1: The percentage of the population estimated to have antibodies against SARS-CoV-2 remained high for UK adults in the week beginning 22 August 2022

Modelled percentage of the adult population with levels of antibodies against SARS-CoV-2 at or above 179 nanograms per millilitre (ng/ml) or 800 ng/ml, by age group, UK countries, 7 December 2020 to 26 August 2022

Notes:

1. All results are provisional and subject to revision.
2. These statistics refer to antibody tests for individuals living in private households. They exclude those in hospitals, care homes or other communal establishments.
3. In Northern Ireland, the number of people sampled is low compared with England, Wales, and Scotland; therefore, adults aged 50 to 69 years are included in the same age group, and those aged 70 years and over are included in the same age group.
4. All estimates are subject to uncertainty, given that a sample is only part of the wider population. A [credible interval](#) gives an indication of the uncertainty of an estimate from data analysis.
5. The denominators used for antibodies are the total for each age group in the sample at that particular time point, then post-stratified by the mid-year population estimate.
6. There was an issue with antibody lab results over the period 10 January to 27 February 2022, which primarily impacted 800 ng/ml estimates. As a result, 800 ng/ml-level estimates are not available for this period, and all other estimates for February 2022 are subject to change because of the re-processing of some results.

In the week beginning 22 August 2022, the percentage of children estimated to have antibodies against SARS-CoV-2 at or above 179 ng/ml and 800 ng/ml remained high for those aged 12 to 15 years, and increased in younger children, across Great Britain.

Figure 2: The percentage of children estimated to have antibodies against SARS-CoV-2 remained high for those aged 12 to 15 years, and has increased in younger children, in the week beginning 22 August 2022

Modelled percentage of children with levels of antibodies against SARS-CoV-2 at or above 179 nanograms per millilitre (ng/ml) or 800 ng/ml, by age group, Great Britain, 7 December 2020 to 26 August 2022

Notes:

1. All results are provisional and subject to revision.
2. These statistics refer to antibody tests for individuals living in private households. They exclude those in hospitals, care homes or other communal establishments.
3. All estimates are subject to uncertainty, given that a sample is only part of the wider population. A [credible interval](#) gives an indication of the uncertainty of an estimate from data analysis.
4. The denominators used for antibody age groups are the total children aged 8 to 11 years and 12 to 15 years, respectively, in the sample at that particular time point, who are then post-stratified by the mid-year population estimate.
5. Estimates show the percentages of children in age groups 8 to 11 years and 12 to 15 years in Great Britain as a whole (England, Wales and Scotland) who would have tested positive for antibodies against SARS-CoV-2 at or above the antibody levels of 179 ng/ml and 800 ng/ml.
6. There was an issue with antibody lab results over the period 10 January to 27 February 2022, which primarily impacted 800 ng/ml estimates. As a result, 800 ng/ml-level estimates are not available for this period, and all other estimates for February 2022 are subject to change because of the re-processing of some results.
7. Estimates for children in age groups 8 to 11 years and 12 to 15 years are not available before 29 November 2021.

[.xlsx](#)

Figure 3 shows the proportion of the adult population estimated to have antibodies to SARS-CoV-2 between the following ranges:

- less than 179 ng/ml (including those with low or no antibodies to SARS-CoV-2)
- from 179 ng/ml up to 800 ng/ml
- from 800 ng/ml up to 2000 ng/ml
- from 2000 ng/ml up to 4000 ng/ml
- from 4000 ng/ml up to 6000 ng/ml
- 6000 ng/ml and above

Each of these ranges is represented by a shaded area. The larger the area, the greater the proportion of people who have antibody levels within this range. This information is shown by age group and country.

Across the UK, most age groups were estimated to have the greatest proportion of people with antibody levels between 800 ng/ml and 2000 ng/ml, in the week beginning 22 August 2022.

Figure 3: The highest antibody levels were seen among the oldest ages across the UK, in the week beginning 22 August 2022

Modelled percentage of the population with levels of antibodies across varying levels from less than 179 nanograms per millilitre (ng/ml) to 6000 ng/ml and above, 2 May to 26 August 2022

Notes:

1. All results are provisional and subject to revision.
2. These statistics refer to antibody tests for individuals living in private households. They exclude those in hospitals, care homes or other communal establishments.
3. All estimates are subject to uncertainty, given that a sample is only part of the wider population. A [credible interval](#) gives an indication of the uncertainty of an estimate from data analysis.
4. The denominators used for antibodies are the total for each age group in the sample at that particular time point, then post-stratified by the mid-year population estimate.
5. The percentages shown in this chart include antibody levels up to, but not including, the upper threshold stated.

3 . Coronavirus (COVID-19) Infection Survey data

[Coronavirus \(COVID-19\) antibody and vaccination data for the UK](#)

Dataset | Released 5 October 2022

Antibody data by UK country and regions in England from the Coronavirus (COVID-19) Infection Survey.

4 . Glossary

Antibodies

We measure the levels of antibodies in people who live in private households to understand who has had coronavirus (COVID-19) in the past and the impact of vaccinations. It takes between two and three weeks after infection or vaccination for the body to make enough antibodies to fight the infection. Antibodies can help prevent individuals from getting the same infection again. Once infected or vaccinated, antibodies remain in the blood at low levels and can decline over time.

SARS-CoV-2

This is the scientific name given to the specific virus that causes COVID-19.

Credible interval

A credible interval gives an indication of the uncertainty of an estimate from data analysis. A 95% credible interval is calculated so that there is a 95% probability of the true value lying in the interval.

5 . Measuring the data

Reference dates

The antibody positivity estimates for the most recent week in this publication include data from 22 to 26 August 2022.

Our [Coronavirus \(COVID-19\) Infection Survey: methodology article](#) provides further information around the survey design, how we process data, and how data are analysed. Our [Quality and Methodology Information](#) explains the strengths and limitations of the data, methods used, and data uses and users.

More [information on measuring the data](#) is available in the Coronavirus (COVID-19) Infection Survey statistical bulletin.

Change in data collection method

Following our recent change to a remote data collection method, we published results comparing estimates produced by study worker home visit data collection only, with those produced by remote data collection only. The 179 nanograms per millilitre (ng/ml) and 800 ng/ml levels were used for this analysis. Between 10 and 29 July 2022, there was no statistical evidence of a difference between estimates of the percentage of the population of Great Britain testing positive for antibodies against SARS-CoV-2 at the 179 ng/ml level produced by remote data collection or study worker home visit data collection. Between 10 and 29 July 2022, there was statistical evidence of a small difference at the 800 ng/ml level, indicating that blood samples collected remotely were slightly more likely to have antibodies against SARS-CoV-2 at or above this level compared with those collected at study worker home visits, in Great Britain. Details of these results can be found in our [Coronavirus \(COVID-19\) Infection Survey quality report: September 2022](#).

Survey data

The analysis on antibodies in this bulletin is based on blood test results taken from a randomly selected subsample of individuals aged 8 years and over who live in private households. The survey excludes those in hospitals, care homes and other communal establishments. The blood samples are used to test for antibodies against SARS-CoV-2.

Antibodies and immunity

Antibody positivity is defined by having a fixed concentration of antibodies in the blood. A negative test result occurs if there are no antibodies, or if antibody levels are too low to reach a level at the time of testing. It does not mean that their antibody level is at zero or that a person has no protection against COVID-19. Additionally, there are other parts of the immune system that will offer protection, for example, a person's T-cell response. This will not be detected by blood tests for antibodies. [A person's immune response is affected by a number of factors](#), including health conditions and age.

Our [blog on antibodies and immunity](#) gives further information on the link between antibodies and immunity and the vaccine programme. Our [blog on vaccine effectiveness](#) provides information on the effectiveness of vaccinations against Alpha and Delta variants, which is based on research conducted by partners from the University of Oxford.

Measuring antibody positivity

Our 179 ng/ml [level is based on research by our academic partners](#) and reflects the percentage of adults who would have been likely to have a strong enough antibody response to provide some protection from getting a new COVID-19 infection with the Delta variant. This level is higher than our previously reported standard level of 42 ng/ml, which was associated with SARS-CoV-2 infection before vaccines became available. Antibody levels below this 179 ng/ml level does not mean that a person has no antibodies or immune protection at all. This antibody level was identified as providing a 67% lower risk of getting a new COVID-19 infection with the Delta variant after two vaccinations with either Pfizer or AstraZeneca vaccines, compared with someone who was unvaccinated and had not had COVID-19 before. It is unlikely that this level will provide equivalent protection against the Omicron variant, and we will keep the level used in our analysis of antibodies under regular review. The 800 ng/ml level is the highest level at which we can produce a historic back-series. We have also introduced estimates of antibody positivity at 2000 ng/ml, 4000 ng/ml and 6000 ng/ml. These levels have been introduced to enable enhanced monitoring of antibody levels and waning. They are not based on academic research on protection against Omicron, as sufficient evidence on this is not yet available.

The [test used for spike antibodies](#) measures their concentration in ng/ml. The antibody level of 179 ng/ml corresponds to 100 binding antibody units (BAU)/ml, using the World Health Organization's (WHO) standardised units (enabling comparison across different antibody assays).

Further information on antibody test levels, and the link between antibodies and infections, can be found in our recent blog post, [The relationship between COVID-19 infections and antibodies: What do the data show?](#)
